

Liquefied Petroleum Gas Sampling Procedures

It has been established that the risk of an incident is much greater when personnel are attempting to draw samples from areas unfamiliar to them, particularly if they attempt to use mis-matched connections. The most common example of this situation is the requirement for shore representatives to draw samples from ship tanks. In November 1988, SIGTTO addressed this problem and published International Recommendation to standardize liquefied gas sampling valves, connections and operations. SIGTTO recommended, inter alia, that ships tank sample connections should terminate in a G 7 female parallel threaded connector to ISO 228/1, and the sampling equipment should terminate in a corresponding male connector. This recommendation has been adopted widely by the industry in the meantime. However, following two separate incidents on board gas carriers carrying out sampling operations within UK ports, the UK MAIB issued Recommendation No. 2007/149 urging SIGTTO to Review and revise guidance provided to the industry on sampling arrangements, taking due account of any standard required by classification societies. The MAIB has published full details of both incidents. Which in summary, in the first case there was an uncontrolled release of VCM from the ships mast due to inadvertent cargo transfer from one tank to another during sampling. In the second case, an incorrectly installed sample valve unscrewed and dropped off when attempting to connect a sample container; the resulting leak could not be controlled as the ships ESD valve had jammed part-open due to an unrelated pre-existing problem that had not been observed. The present document discusses the following aspects of sampling: -Basic reasons why cargo samples are taken -Sampling connections - Open and Closed loop systems -Types of sample containers

-Recommended standard sample connections
-Safe procedures for taking samples
